1. Dataset visualization

Our relfectance field is learned from a light-stage dataset containing 350 identities, captured from 8 camera viewpoints and illuminated by 150 point light sources one at a time (see Fig. 1). The dataset was originally proposed in Weynrich *et al.* [5], with just 149 identities. The dataset we use, however, contains 201 additional identities. Throughout our work we use 300 identities for training, 10 for validation and the rest for test.

2. Network details

Please refer to Tables.1 and 2 for detailed architectures of the geometry and reflectance networks.

3. Video results

We provide a compiled video in the project page¹ consisting of following results.

3.1. Relighting with densely sampled OLATs

Even though our reflectance model is trained using only 150 point light sources, we can sample any arbitrary number of OLATs using the light direction input. In the video, we sample results for 1024 point light sources. Here, we move the light source from top to bottom in a spiral manner. We show result for 18 identities shot in-the-wild.

3.2. View dependent effects

Please watch the video, which demonstrates view dependent effects. Here, we keep the light source fixed and only change the camera pose. Note how the specular component around the nose region changes as the camera moves. Results also show changes in sub surface component as the camera pose changes (e.g. change in soft shadows).

3.3. Relighting with environment maps

Please watch the video, where we relight several identities with environment map. Here we also change the viewing angle, which shows the view dependent capabilities of our method. We also relight dynamic video of the faces, which shows the generalization capability of our method for different expressions.

4. Ablative Study: VGG-based imageNet and light feature Loss

We assess the impact of the feature losses used in our reflectance learning. One of the feature losses (L_I) is based on a VGG network trained on ImageNet [1]. The other feature loss \mathcal{L}_L is based on a VGG network trained to predict lighting direction of OLATs [2]. We evaluate the OLAT reconstructions error using Si-MSE on the same test dataset used in Table. 1 in the main paper. We report results for renderings with same and different input head pose. Tab. 2 shows that the best performance is obtained when both losses are used. This is especially case when rendering with a head pose different from the input.

5. OLAT comparison:

We project the OLAT lights to the spherical harmonic space and perform a comparison of relighting results. Fig. 2 shows that our method can capture physically correct selfshadows and other global effects to synthesize photo realistic image.

6. High-Fidelity Facial Reflectance and Geometry Inference From an Unconstrained Image

The approach of Yamaguchi *et al.* [6] regresses diffuse and specular albedo maps of a face from an image. The ground truth during training is obtained using a light stage

Table 1. Geometry network details.

Figure 2. We use spherical harmonic approximation of point light source to synthesize comparitive method. Observe that our method captures physically correct shadows and other global illumination effects photo realistically.

dataset. Since only the diffuse and specular components are modeled, other higher view-dependent effects is ignored. Since this approach cannot predict the environment light from the image, it is difficult to compare directly using a reference image for lighting. Each approach uses a different coordinate system for representing meshes and the light, making it difficult to render the results of both methods under the same lighting. For a qualitative comparison, we manually change the lights in the scene in order to get visually similar results. As can be see in Fig. 3, our results are more natural with better sub-surface scattering and soft shadows (nose, eyes, chin). The visualization requires an expensive rendering step which computes the interactions between the lighting and albedo. Our results, on the other hand, already take the lighting into account. This offers several advantages. First, our rendering is much faster than Yamaguchi *et al.* Second, our final rendering is differentiable, which can be used as a component in any other learning task. The rendering step is not differentiable for Yamaguchi *et al.*

7. Additional comparisons

We compare to the single image relighting approach of Zhou *et al.* [8]. Since this approach uses a spherical approximation to represent the lights, our relighting results are more natural and reflect the target lighting better, see Fig 4. In addition, image relighting approaches do not model view-dependent effects and thus, cannot change the head pose.

We also compare the quality of our geometry reconstructions with MoFA [4] in Tab. 3. MoFA was trained on our training dataset. The errors are computed on the BU-3DFE dataset [7]. We use the same metric as used in Tewari *et* al. [3], where a dense correspondence map between the re-

constructed and ground-truth mesh templates is precomputed for evaluation. The translation, scale, and orientation of the reconstructed and ground-truth meshes are aligned before computing the errors. While MoFA achieves slightly better numbers, its reflectance quality is limited as demonstrated in the main paper.
